Machine Learning (ML)

Hybrid ML approach for a sea-ice observation operator (used to simulate satellite observations in Numerical Weather Prediction/DA systems)

Geer, A. J. (2024a). Simultaneous inference of sea ice state and surface emissivity model using machine learning and data assimilation.

Polar regions

Arctic amplification drives rapid changes in surface conditions (e.g., sea-ice extent), with implications for regional and global weather, and the emergence of new maritime routes requiring reliable forecasts.

AMSU-A on board
METOP-B. Channels
23V, 31V, 50V, 53V

> 50.5°N
latitude,
excluding
land points

*Includes: observation error tuning, per-channel background bias correction (sea-ice & open ocean), background error, emissivity lower bound at 23V and constant penalty against false sea-ice

01/04/2024

Experiment 1

The first major objective was to **successfully run** the hybrid ML model with **AMSU-A inputs** and obtain physically realistic outputs.

Even without AMSU-A-specific tuning or explicit scan-angle dependency, **good agreement** is achieved at **low frequencies**.

At **higher frequencies**, **increased biases** and missing spatial structures are observed

likely linked to stronger atmospheric sensitivity of these channels and the need for further model refinement.

01/04/2024

Experiment 1

Experiment 3

Impact of model parameter tuning

- Annual mean Obs–Sim differences are reduced by **91–99%** in Experiment 3 relative to Experiment 1 (channels 31V, 50V and 53V).
- Parameter tuning plays a key role in improving model performance

AMSU-A onboard METOP-B
Channel 1 (23V)
01/04/2024 - 31/03/2025

Impact of angle dependency

Annual statistics

Large viewing angles

Reduction in mean bias

exp1 [K]

Observed BT
[K]

- The hybrid ML sea-ice observation operator was successfully implemented with AMSU-A inputs, producing physically consistent outputs.
- Even without AMSU-A-specific tuning or scan-angle dependency, the initial configuration showed good agreement at low frequencies (23V, 31V), while larger biases and missing spatial structures remained at higher frequencies.
- Parameter tuning is a key driver of model performance, reducing annual mean Obs–Sim differences by 91–99% for channels 31V, 50V, and 53V.
- Including scan-angle dependency further improves performance at large viewing angles, although small degradations near nadir require further investigation.

Machine Learning (ML)

Motivation

New focus: ML-based fast ice detection

Methodology

Ice charts & Synthetic Aperture Radar (SAR) data (e.g. Sentinel-1)

Results

Fully ML based approach (U-net architecture)

Conclusions

Greenland and the Canadian Arctic Archipelago

08/02/2021 08:21:07H

10/02/2021 18:35:06H

1) Identify days and regions characterized by fast ice based on operational ice charts

2) Collocate SAR imagery covering these areas, including images from preceding days to capture temporal persistence

3) Assemble these data into a dedicated ML training dataset

Thank you
